Math 333 Test II, Summer ’09 (with Solutions)

Dr. Holmes

July 4, 2010

The exam will begin at 11:50 am and end at 1:30 pm. You may use a writing instrument and a plain scientific calculator without graphing or symbolic computation capability. Write your name on the exam paper and on the blue book(s) you use, and return both at the end of the exam. Be sure to record the ID number on your blue book which will be used to post your grade on my web page. Write all work in your blue book(s): work written on the test paper will not be noticed. Cell phones must be turned off and out of sight.
1. Sketch the direction field for the differential equation

\[ y' = -(y + 1)(y - 3). \]

Sketch in the equilibrium solutions. Identify each equilibrium solution as stable or unstable. Sketch in representative solutions of each kind. There is no need to solve the equation: these are purely qualitative sketches.

**Solution:** The equilibrium solutions are at \( y = -1 \) and \( y = 3 \). Typical solution curves go down toward \( y = 3 \), up from \( y = -1 \) toward \( y = 3 \), and down from \( y = -1 \). I will put a sketch on my office door when I next go by the office.

2. A circuit has a resistor (R=2) and a coil (L=1) in it. At time 0, there is no current in the circuit. From time \( t=0 \) to \( t=3 \), a constant voltage of 20 is supplied; after time 3 no voltage is supplied. Set up appropriate differential equations and initial value problems to find formulas for the current in the circuit at time \( t \) (a formula for \( 0 \leq t \leq 3 \) and a formula for \( t \geq 3 \)).

The form of the differential equation here is \( LI' + RI = E(t) \).

**Solution:** Please note in this and following problems that I will not necessarily supply you with the forms of the equations as I did in Summer ’09.

To find the current from \( t = 0 \) to \( t = 3 \), solve the initial value problem \( I' + 2I = 20; I(0) = 0 \):

\[
I'e^{2t} + 2Ie^{2t} = 20e^2t
\]

\[
(Ie^{2t})' = 20e^{2t}
\]

\[
Ie^{2t} = 10e^{2t} + C
\]

\[
I = 10 + Ce^{-2t}
\]
\[ I = 10 - 10e^{-2t} \]

(since \( I(0) = 0 \))

This works for \( t = 0 \) to \( t = 3 \)

we know the current at \( t = 3 \) is \( 10 - 10e^{-6} \)

To find the current from \( t = 3 \) on, solve the initial value problem

\( I' + 2I = 0; I(3) = 10 - 10e^{-6} \)

solution to the differential equation is \( ke^{-2t} \)

\( I(3) = ke^{-6} = 10 - 10e^{-6} \) so \( k = 10e^6 - 10 \)

solution is \( I(t) = 10 - 10e^{-2t} \) for \( t \) between 0 and 3, \( I(t) = (10e^6 - 10)e^{-2t} \) for \( t > 3 \).

3. Find the general solution for each of the following equations.

(a) \[ y'' + 3y' + 2y = 0 \]

**Solution** \( c_1e^{-t} + c_2e^{-2t} \)

(b) \[ y'' - 6y' + 9y = 0 \]

**Solution:** \( c_1e^{3t} + c_2te^{3t} \)

(c) \[ y'' + 2y' + 5y = 0 \]

**Solution** solution to the quadratic is \(-1 \pm 2i \) so \( c_1e^{-t}\cos(t) + c_2e^{-t}\sin(t) \)

4. Find the solution to the initial value problem

\[ y'' + 3y' + 2y = 0; y(0) = 3; y'(0) = -4. \]

**Solution:**

\[ y(t) = c_1e^{-t} + c_2e^{-2t} \]

\[ y'(t) = -c_1e^{-t} - 2c_2e^{-2t} \]

\[ y(0) = c_1 + c_2 = 3 \]

\[ y'(0) = -c_1 - 2c_2 = -4 \]
5. Find the general solution of the equation

\[ y'' + 3y' + 2y = \sin(2t). \]

**Solution:**
The solution of the homogeneous equation is \( c_1 e^{-t} + c_2 e^{-2t} \)
The particular solution will be of the form \( A \cos(2t) + B \sin(2t) \)

\[
\begin{align*}
y &= A \cos(2t) + B \sin(2t) \\
y' &= -2A \sin(2t) + 2B \cos(2t) \\
y'' &= -4A \cos(2t) - 4B \sin(2t)
\end{align*}
\]

\[
-4A \cos(2t) - 4B \sin(2t) - 6A \sin(2t) + 6B \cos(2t) + 2A \cos(2t) + 2B \sin(2t) = \sin(2t)
\]

\[-2A + 6B = 0 \]

\[6A - 2B = 1\]

\[-6A + 18B = 0 \text{ (multiply first by 3)}\]

\[16B = 1 \text{ (add)}\]

so \( B = \frac{1}{16} \)

\( A = \frac{3}{16} \) (solve in either of the equations)

and the general solution is \( \frac{3}{16} \cos(2t) + \frac{1}{16} \sin(2t) + c_1 e^{-t} + c_2 e^{-2t} \)

6. A mass of 2 kg is suspended at the end of a spring with constant 18. The spring is allowed to come to equilibrium: at time 0 the spring is set into motion from equilibrium position at velocity 0.5 m/sec. Neglecting friction, determine the position of the weight at time \( t \). State the amplitude and frequency of the oscillation of the spring.

What coefficient of friction \( \mu \) would need to be introduced for this system to become critically damped?

The general form of the equation here is \( mx'' + \mu x' + kx = 0 \).

**Solution:**
The equation without friction is \( 2x'' + 18x = 0 \) or \( x' + 9x = 0 \), to which we know the solutions are \( c_1 \cos(3t) + c_2 \sin(3t) \).
\[ x(t) = c_1 \cos(3t) + c_2 \sin(3t) \]
\[ x'(t) = -3c_1 \sin(3t) + 3c_2 \cos(3t) \]
\[ x(0) = c_1 = 0 \]
\[ x'(0) = 3c_2 = 0.5 \]
so \( c_1 = 0; \ c_2 = \frac{1}{6} \)
\[ x(t) = \frac{1}{6} \sin(3t) \]
To make the system critically damped, we need to choose \( \mu \) to make the quadratic a perfect square.
\[ 2x'' + \mu x' + 18x = 0 \]
polynomial is \( 2\lambda^2 + \mu \lambda + 18 = 2(\lambda^2 + \frac{\mu}{2} \lambda + 9) \) which will be a perfect square if \( \frac{\mu}{2} = 6 \), so \( \mu = 12 \).
